### COS 217 Midterm

#### When/where?

• In class, Wed. March 13; split between here and Friend 004/008

#### What?

- C programming, including string and stdio
- Numeric representations and types in C
- Programming in the large: modularity, building, testing, debugging
- Readings, lectures, precepts, assignments, through *this week*
- Mixture of short-answer questions and writing snippets of code

#### How?

- Closed book and notes
- No electronic anything
- Interfaces of relevant functions will be provided

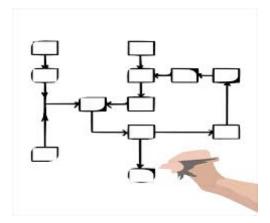

Old exams and study guide will be posted on schedule page

### **Princeton University**

**Computer Science 217: Introduction to Programming Systems** 

### **Modules and Interfaces**

The material for this lecture is drawn, in part, from *The Practice of Programming* (Kernighan & Pike) Chapter 4

### **Goals of this Lecture**

#### Help you learn:

How to create high quality modules in C

### Why?

- Abstraction is a powerful (the only?) technique available for understanding large, complex systems
- A software engineer knows how to find the abstractions in a large program
- A software engineer knows how to convey a large program's abstractions via its modularity

## Agenda

#### A good module:

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

## **Encapsulation**

### A well-designed module encapsulates data

- An interface should hide implementation details
- A module should use its functions to encapsulate its data
- A module should not allow clients to manipulate the data directly

### Why?

- Clarity: Encourages abstraction
- Security: Clients cannot corrupt object by changing its data in unintended ways
- Flexibility: Allows implementation to change even the data structure – without affecting clients

## **Abstract Data Type (ADT)**

#### A data type has a *representation*

```
struct Node {
   int key;
   struct Node *next;
};

struct List {
   struct Node *first;
};
```

#### and some operations:

```
struct List * new(void) {
   struct List *p;
   p=(struct List *)malloc (sizeof *p);
   assert (p!=NULL);
   p->first = NULL;
   return p;
}

void insert (struct list *p, int key) {
   struct Node *n;
   n = (struct Node *)malloc(sizeof *n);
   assert (n!=NULL);
   n->key=key; n->next=p->first; p->first=n;
}
```

An abstract data type has a hidden representation; all "client" code must access the type through its interface:

### Barbara Liskov, a pioneer in CS

"An **abstract data type** defines a class of abstract objects which is completely characterized by the operations available on those objects. This means that an abstract data type can be defined by defining the characterizing operations for that type."

Barbara Liskov and Stephen Zilles.
"Programming with Abstract Data Types."

ACM SIGPLAN Conference on Very

High Level Languages, April 1974.

# **Encapsulation with ADTs (wrong!)**

#### list.h

If you put the representation here, then it's not an **abstract** data type, it's just a data type.

(Many C programmers program this way because they don't know any better.)

#### client.c

```
#include "list.h"
int f(void) {
   struct List *p, *q;
   p = new();
   q = new();
   insert (p,6);
   insert (p,7);
   insert (q,5);
   concat (p,q);
   concat (q,p);
   return nth_key(q,1);
}
```

#### list\_linked.c

```
#include "list.h"

struct List * new(void) {
   struct List *p = (struct List *)malloc(sizeof(*p));
   p->first=NULL;
   return p;
}

void insert (struct List *p, int key) {...}

void concat (struct List *p, *q) { ... }

int nth_key (struct List *p, int n) { ... }
```

# **Encapsulation with ADTs (right!)**

#### list.h

Including only the declaration in header file **enforces** the abstration: it keeps clients from accessing fields of the struct, allowing implementation to change

#### client.c

```
#include "list.h"

int f(void) {
    struct List *p, *q;
    p = new();
    q = new();
    insert (p,6);
    insert (p,7);
    insert (q,5);
    concat (p,q);
    concat (q,p);
    return nth_key(q,1);
}
```

#### list\_linked.c

#include "list.h"

```
struct Node {int key; struct Node *next;};
struct List {struct Node *first;};

struct List * new(void) {
   struct List *p = (struct List *)malloc(sizeof(*p));
   p->first=NULL;
   return p;
}

void insert (struct List *p, int key) {...}

void concat (struct List *p, *q) { ... }

int nth_key (struct List *p, int n) { ... }
```

### **Specifications**

If you can't see the representation (or the implementations of insert, concat, nth\_key), then how are you supposed to know what they do?

A List *p* **represents** a sequence of integers  $\sigma$ .

Operation new() returns a list *p* representing the empty sequence.

Operation insert(p, i), if p represents  $\sigma$ , causes p to now represent  $i \cdot \sigma$ .

Operation concat(p, q), if p represents  $\sigma_1$  and q represents  $\sigma_2$ , causes p to represent  $\sigma_1 \cdot \sigma_2$  and leaves q representing  $\sigma_2$ .

Operation nth\_key(p, n), if p represents  $\sigma_1 \cdot i \cdot \sigma_2$  where the length of  $\sigma_1$  is n, returns i; otherwise (if the length of the string represented by p is  $\leq n$ ),

it returns an arbitrary integer.

This is OK! Client programs relying on unspecified behavior might break with a new implementation.

Doctor, it hurts when I do this

### **Reasoning About Client Code**

List of specifications allows for reasoning about the effects of client code.

```
int f(void) {
   struct List *p, *q;
   p = new();
   q = new();
   insert (p,6);
   insert (p,7);
   insert (q,5);
   concat (p,q);
   concat (q,p);
   return nth_key(q,1);
}
```

```
p:[]
p:[] q:[]
p:[6] q:[]
p:[7,6] q:[]
p:[7,6] q:[5]
p:[7,6,5] q:[]
p:[] q:[7,6,5]
return 6
```

## **Object-Oriented Thinking**

C is not inherently an object-oriented language, but can use language features to encourage object-oriented thinking

```
typedef struct List *List_T;

List_T new(void);

void insert (List_T p, int key);

void concat (List_T p, List_T q);

int nth_key (List_T p, int n);

void free_list (List_T p);
```

"Opaque" pointer type

- Interface provides List\_T abbreviation for client
  - Interface encourages client to think of objects (not structures)
     and object references (not pointers to structures)
- Client still cannot access data directly; data is "opaque" to the client

## Agenda

#### A good module:

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

# Resource Management

#### A well-designed module manages resources consistently

- A module should free a resource if and only if the module has allocated that resource
- Examples

### Why?

- Allocating and freeing resources at different levels is error-prone
  - Forget to free memory ⇒ memory leak
  - Forget to allocate memory ⇒ dangling pointer, seg fault
  - Forget to close file ⇒ inefficient use of a limited resource
  - Forget to open file ⇒ dangling pointer, seg fault

### Resource Management in stdio

fopen() allocates memory for FILE struct, obtains file descriptor from OS

fclose() frees memory associated with FILE struct, releases file descriptor back to OS

# Resources in Assignment 3

Who allocates and frees the key strings in symbol table?

### Reasonable options:

- (1) Client allocates and frees strings
  - SymTable\_put() does not create copy of given string
  - SymTable\_remove() does not free the string
  - SymTable\_free() does not free remaining strings
- (2) SymTable object allocates and frees strings
  - SymTable\_put() creates copy of given string
  - SymTable\_remove() frees the string
  - SymTable\_free() frees all remaining strings

### Our choice: (2)

 With option (1) client could corrupt the SymTable object (as described in last lecture)

### **Passing Resource Ownership**

Violations of expected resource ownership should be noted explicitly in function comments

```
somefile.h
void *f(void);
   This function allocates memory for
   the returned object. You (the caller)
   own that memory, and so are responsible
   for freeing it when you no longer
   need it. */
```

# Agenda

#### A good module:

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

# Consistency

### A well-designed module is consistent

- A function's name should indicate its module
  - Facilitates maintenance programming
    - Programmer can find functions more quickly
  - Reduces likelihood of name collisions
    - From different programmers, different software vendors, etc.
- A module's functions should use a consistent parameter order
  - Facilitates writing client code

### Consistency in string.h

#### string

```
consistent?
/* string.h */
size t strlen(const char *s);
char *strcpy(char *dest, const char *src);
char *strncpy(char *dest, const char *src, size t n);
char
      *strcat(char *dest, const char *src);
char
      *strncat(char *dest, const char *src, size_t n);
int
       strcmp(const char *s1, const char *s2);
int
     strncmp(const char *s1, const char *s2, size t n);
char
      *strstr(const char *haystack, const char *needle);
void
      *memcpy(void *dest, const void *src, size t n);
int
      memcmp(const void *s1, const void *s2, size t n);
```

Is parameter order consistent?

Are function names

# Agenda

#### A good module:

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

### **Minimization**

### A well-designed module has a minimal interface

- Function declaration should be in a module's interface if and only if:
  - The function is necessary for functionality, or
  - The function is necessary for clarity of client code

### Why?

More functions ⇒ higher learning costs, higher maintenance costs

### iClicker Question

Q: Assignment 3's interface has both SymTable\_get() (which returns NULL if the key is not found) and SymTable\_contains() – is the latter necessary?

- A. No should be eliminated
- B. Yes necessary for functionality
- C. Yes necessary for efficiency
- D. Yes necessary for clarity

### iClicker Question

Q: Assignment 3 has **SymTable\_hash()** defined in implementation, but not interface. Is this good design?

- A. No should be in interface to enable functionality
- B. No should be in interface to enable clarity
- C. Yes should remain an implementation detail

# Agenda

#### A good module:

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

## **Error Handling**

A well-designed module detects and handles/reports errors

#### A module should:

- Detect errors
- Handle errors if it can; otherwise...
- Report errors to its clients
  - A module often cannot assume what error-handling action its clients prefer

# Handling Errors in C

### C options for detecting errors

- if statement
- assert macro

### C options for handling errors

- Write message to stderr
  - Impossible in many embedded applications
- Recover and proceed
  - Sometimes impossible
- Abort process
  - Often undesirable

#### C options for **reporting** errors to client (calling function)

• Set global variable?

- Easy for client to forget to check
- Bad for multi-threaded programming

#### C options for **reporting** errors to client (calling function)

• Use function return value?

```
int div(int dividend, int divisor, int *quotient)
{    if (divisor == 0)
        return 0;
    ...
    *quotient = dividend / divisor;
    return 1;
}
...
successful = div(5, 3, &quo);
if (! successful)
    /* Handle the error */
```

Awkward if return value has some other natural purpose

#### C options for **reporting** errors to client (calling function)

• Use call-by-reference parameter?

Awkward for client; must pass additional argument

### C options for **reporting** errors to client (calling function)

• Call assert macro?

```
int div(int dividend, int divisor)
{  assert(divisor != 0);
  return dividend / divisor;
}
...
quo = div(5, 3);
```

- Asserts could be disabled
- Error terminates the process!

C options for **reporting** errors to client (calling function)

No option is ideal

### **User Errors**

#### Our recommendation: Distinguish between...

#### (1) User errors

- Errors made by human user
- Errors that "could happen"
- Example: Bad data in stdin
- Example: Too much data in stdin
- Example: Bad value of command-line argument
- Use if statement to detect
- Handle immediately if possible, or...
- Report to client via return value or call-by-reference parameter
  - Don't use global variable

### **Programmer Errors**

#### (2) Programmer errors

- Errors made by a programmer
- Errors that "should never happen"
- Example: pointer parameter should not be **NULL**, but is
- For now, use assert to detect and handle
  - More info later in the course

#### The distinction sometimes is unclear

- Example: Write to file fails because disk is full
- Example: Divisor argument to div() is 0

Default: user error

# **Error Handling in List**

```
typedef struct List *List_T;
List_T List_new(void);
void List_insert (List_T p, int key);
void List_concat (List_T p, List_T q);
int List_nth_key (List_T p, int n);
void List_free (List_T p);
```

add assert(p) in each of the functions.... try to protect against bad clients

```
void List_insert (List_T p, int key) {
   assert(p);
   . . .
}
```

## **Error Handling in List**

```
typedef struct List *List_T;
List_T List_new(void);
void List_insert (List_T p, int key);
void List_concat (List_T p, List_T q);
int List_nth_key (List_T p, int n);
void List_free (List_T p);
```

Operation nth\_key(p,n), if p represents  $\sigma_1 \cdot i \cdot \sigma_2$  where the length of  $\sigma_1$  is n, returns i; otherwise (if the length of the string represented by p is  $\leq n$ ), returns an arbitrary integer.

- This error-handling in List\_nth\_key is a bit lame.
- How to fix it? Some choices:
  - int List\_nth\_key (List\_T p, int n, int \*error);
  - Or, perhaps better: add an interface function,

int List\_length (List\_T p); and then,

Operation nth\_key(p,n), if p represents  $\sigma_1 \cdot i \cdot \sigma_2$  where the length of  $\sigma_1$  is n, returns i; otherwise (if the length of the string represented by p is  $\leq n$ ), it fails with an assertion failure or abort().

# Agenda

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

# **Establishing Contracts**

### A well-designed module establishes contracts

- A module should establish contracts with its clients
- Contracts should describe what each function does, esp:
  - Meanings of parameters
  - Work performed
  - Meaning of return value
  - Side effects

## Why?

- Facilitates cooperation between multiple programmers
- Assigns blame to contract violators!!!
  - If your functions have precise contracts and implement them correctly, then the bug must be in someone else's code!!!

#### How?

• Comments in module interface

## **Contracts in List**

```
/* list.h */
/* Return the n'th element of the list p,
if it exists. Otherwise (if n is
negative or >= the length of the list),
abort the program. */
int List_nth_key (List_T p, int n);
```

#### Comment defines contract:

- Meaning of function's parameters
  - p is the list to be operated on; n is the index of an element
- Obligations of caller
  - make sure n is in range; (implicit) make sure p is a valid list
- Work performed
  - Return the n'th element.
- Meaning of return value
- Side effects
  - (None, by default)

# **Contracts in List**

```
/* list.h */
/* If 0 <= n < length(p), return the n'th element of
the list p and set success to 1. Otherwise (if n is
out of range) return 0 and set success to 0. */
int List_nth_key (List_T p, int n, int *success);</pre>
```

#### Comment defines contract:

- Meaning of function's parameters
  - p is the list to be queried; n is the index of an element; success is an error flag
- Obligations of caller
  - (implicit) make sure p is a valid List
- Work performed
  - Return the n'th element; set success appropriately
- Meaning of return value
- Side effects
  - Set success

# Agenda

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

# **Strong Cohesion**

# A well-designed module has strong cohesion

A module's functions should be strongly related to each other

## Why?

Strong cohesion facilitates abstraction

# **Strong Cohesion Examples**

#### List

(+) All functions are related to the encapsulated data

### string.h

- (+) Most functions are related to string handling
- (-) Some functions are not related to string handling: memcpy(), memcmp(), ...
- (+) But those functions are similar to string-handling functions

#### stdio.h

- (+) Most functions are related to I/O
- (-) Some functions don't do I/O: sprintf(), sscanf()
- (+) But those functions are similar to I/O functions

### **SymTable**

(+) All functions are related to the encapsulated data

# Agenda

- Encapsulates data
- Manages resources
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion (if time)
- Has weak coupling (if time)

# **Weak Coupling**

### A well-designed module has weak coupling

- Module should be weakly connected to other modules in program
- Interaction within modules should be more intense than interaction among modules

### Why? Theoretical observations

- Maintenance: Weak coupling makes program easier to modify
- Reuse: Weak coupling facilitates reuse of modules

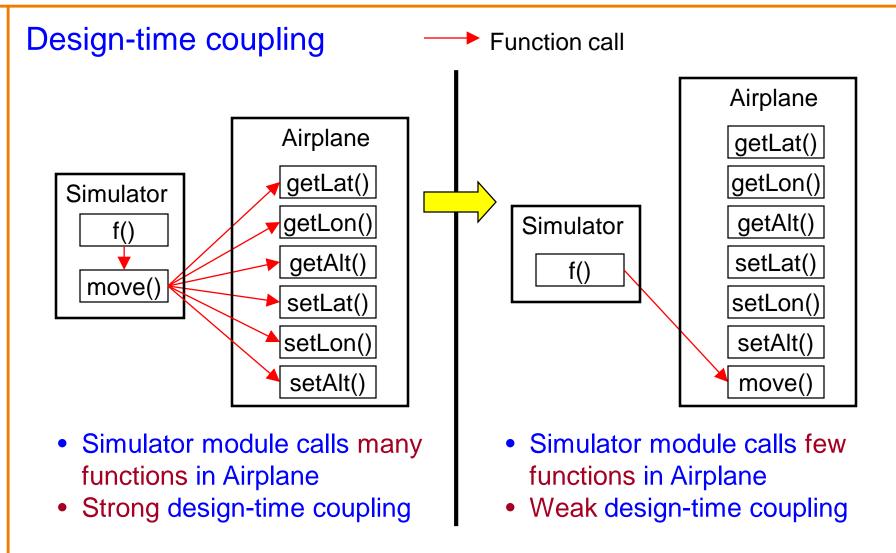

### Why? Empirical evidence

Empirically, modules that are weakly coupled have fewer bugs

Examples (different from previous)...

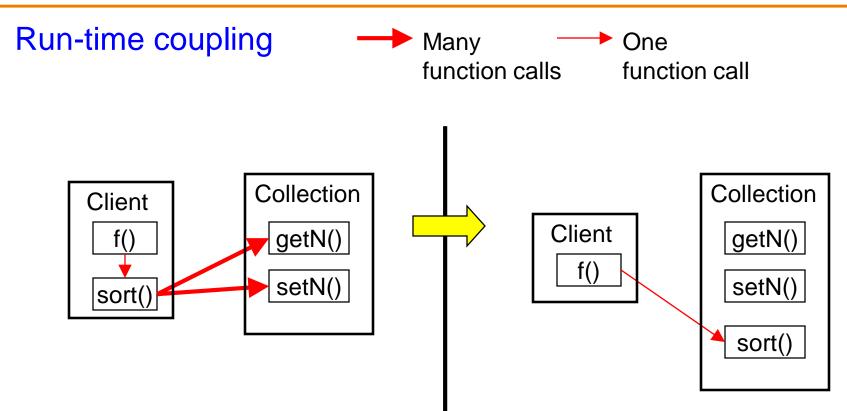

# Weak Coupling Example 1

# Weak Coupling Example 2

- Client module makes many calls to Collection module
- Strong run-time coupling

- Client module makes few calls to Collection module
- Weak run-time coupling

# Weak Coupling Example 3

### Maintenance-time coupling

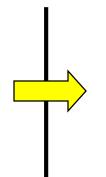

Client MyModule

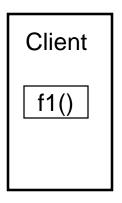

f1()

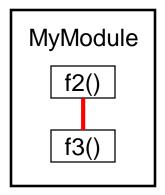

f2()

f3()

- Maintenance programmer changes Client and MyModule together frequently
- Strong maintenance-time coupling

- Maintenance programmer changes Client and MyModule together infrequently
- Weak maintenance-time coupling

# **Achieving Weak Coupling**

### Achieving weak coupling could involve refactoring code:

- Move code from client to module (shown)
- Move code from module to client (not shown)
- Move code from client and module to a new module (not shown)

# **Summary**

- Encapsulates data
- Is consistent
- Has a minimal interface
- Detects and handles/reports errors
- Establishes contracts
- Has strong cohesion
- Has weak coupling
